Learning from Imbalanced Data Sets

Classification with Imbalanced Data Sets Presentation

In a concept-learning problem, the data set is said to present a class imbalance if it contains many more examples of one class than the other.

There exist many domains that do not have a balanced data set. There are a lot of problems where the most important knowledge usually resides in the minority class.

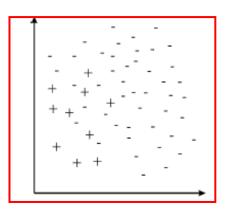

Ej.: Detection of uncommon diseases presents Imbalanced data: Few sick persons and lots of healthy persons.

Some real-problems: Fraudulent credit card transactions, Learning word pronunciation, Prediction of telecommunications equipment failures, Detection oil spills from satellite images, Detection of Melanomas, Intrusion detection, Insurance risk modeling, Hardware fault detection

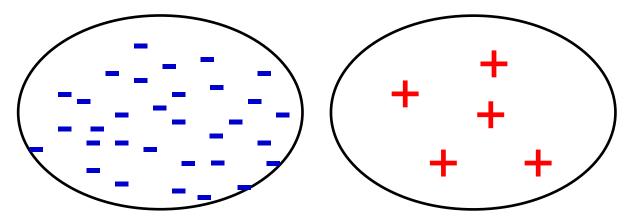

Classification with Imbalanced Data Sets Presentation

Such a situation introduce challenges for typical classifiers (such as decision tree) "systems that are designed to optimize overall

accuracy without taking into account the relative distribution of each class".

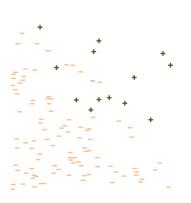

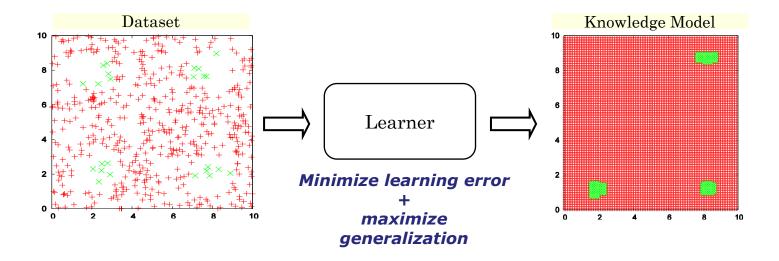

As a result, these classifiers tend to ignore small classes while concentrating on classifying the large ones accurately.

Why learning from imbalanced data-sets might be difficult?

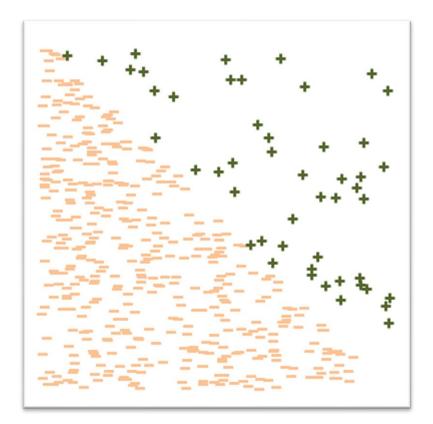

- 1. Search process guided by global error rates.
- 2. Classification rules over the positive class are highly specialized.
- 3. Classifiers tend to ignore small classes concentrating on classifying large ones accurately

Why learning from imbalanced data-sets might be difficult?

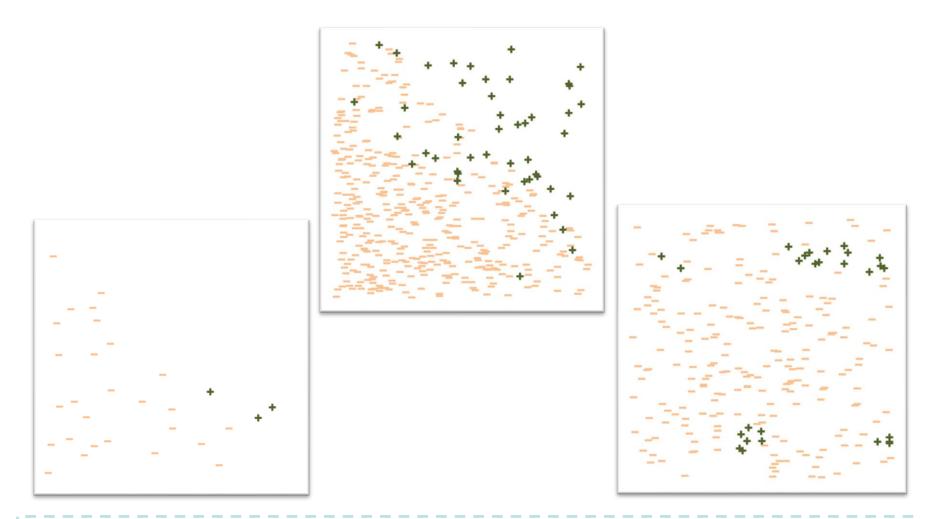

- Skewed class distribution:
 - Measured by the fraction between majority and minority samples
 - Imbalance ratio (IR)
- Intrinsic Data Characteristics
 - Not only imbalance hinders classification performance

• IR ≈ 9

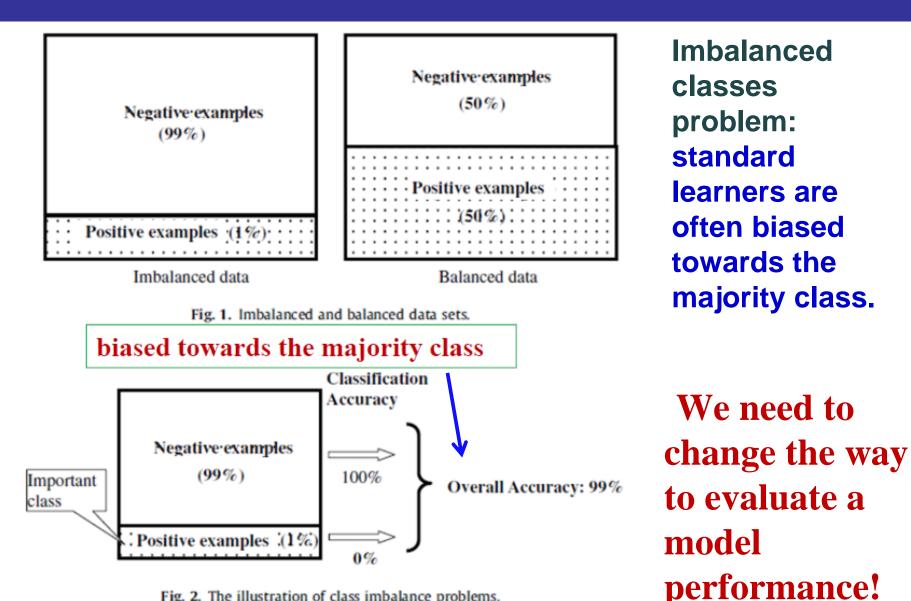

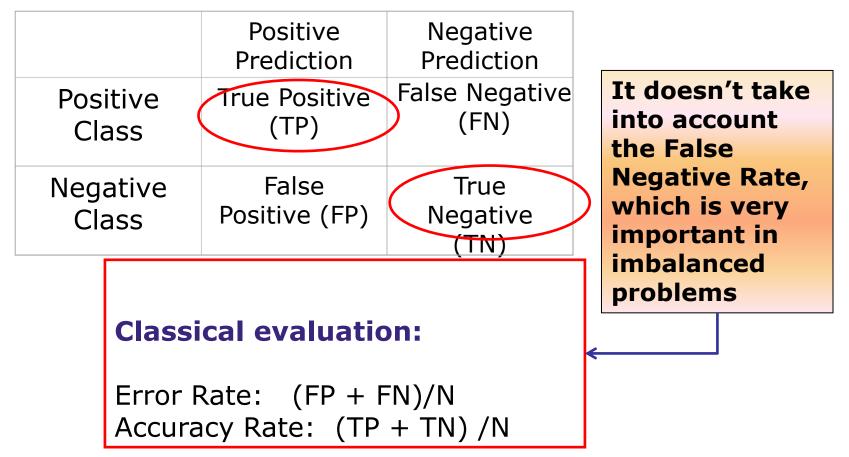

Fig. 2. The illustration of class imbalance problems.

How can we evaluate an algorithm in imbalanced domains?

Confusion matrix for a two-class problem

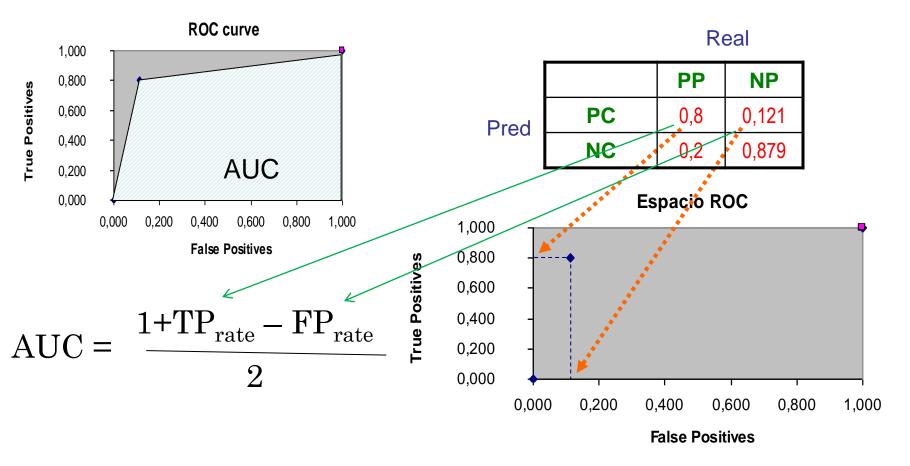

Imbalanced evaluation based on the geometric mean:

Positive true ratio: $a^+ = TP/(TP+FN)$
Negative true ratio: $a^- = TN / (FP+TN)$
Sensitivity = $\frac{TP}{TP + FN}$ Evaluation function:True ratio
 $g = \sqrt{(a^+ \cdot a^-)}$ Sensitivity = $\frac{TN}{TN + FP}$ Precision = TP/(TP+FP)
Recall = TP/(TP+FN)Specificity = $\frac{TN}{TN + FP}$ F-measure:(2 x precision x recall) / (recall + precision)

Cost-sensitive learning Final comments

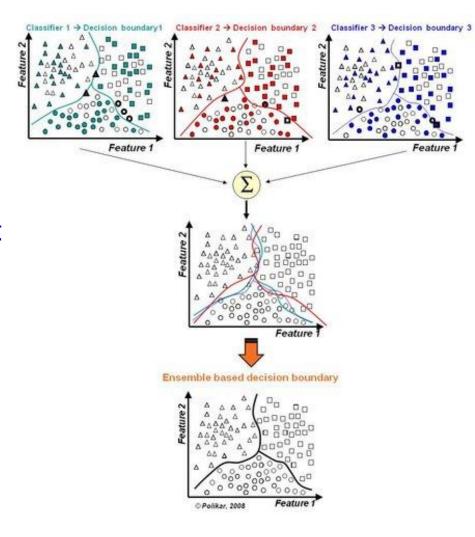

- Preprocessing and cost-sensitive learning improve the base classifier.
- No differences among the different preprocessing techniques.
- Both preprocessing and cost-sensitive learning are good and equivalent approaches to address the imbalance problem.
- In most cases, the preliminary versions of hybridization techniques do not show a good behavior in contrast to standard preprocessing and cost sensitive.

Some authors claim: "Cost-Adjusting is slightly more effective than random or directed over- or undersampling although all approaches are helpful, and directed oversampling is close to cost-adjusting". Our study shows similar results.

V. López, A. Fernandez, J. G. Moreno-Torres, F. Herrera, **Analysis of preprocessing vs. cost-sensitive learning for imbalanced classification. Open problems on intrinsic data characteristics**. *Expert Systems with Applications 39:7 (2012) 6585-6608.*

Ensemble-based classifiers try to improve the performance of single classifiers by inducing several classifiers and combining them to obtain a new classifier that outperforms every one of them. Hence, the basic idea is to construct several classifiers from the original data and then aggregate their predictions when unknown instances are presented. This idea follows human natural behavior which tend to seek several opinions before making any important decision.

Our proposal:

We develop a new ensemble construction algorithm (**EUSBoost**) based on RUSBoost, one of the simplest and most accurate ensemble, combining random undersampling with Boosting algorithm.

Our methodology aims to improve the existing proposals enhancing the performance of the base classifiers by the usage of the evolutionary undersampling approach.

Besides, we promote diversity favoring the usage of different subsets of majority class instances to train each base classifier.

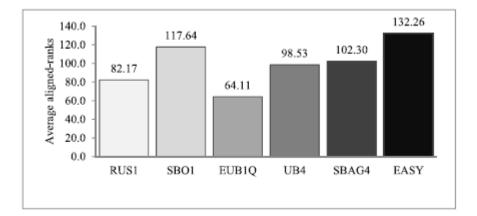

Figure: Average alignedranks of the comparison between EUSBoost and the state-of-the-art ensemble methods.

M. Galar, A. Fernandez, E. Barrenechea, F. Herrera, **EUSBoost: Enhancing Ensembles for Highly Imbalanced Data-sets by Evolutionary Undersampling**. *Pattern Recognition 46:12* (2013) 3460–3471

Emsembles to address class imbalance Final comments

- Ensemble-based algorithms are worthwhile, improving the results obtained by using data preprocessing techniques and training a single classifier.
- The use of more classifiers make them more complex, but this growth is justified by the better results that can be assessed.
- We have to remark the good performance of approaches such as RUSBoost or SmoteBagging, which despite of being simple approaches, achieve higher performance than many other more complex algorithms.
- We have shown the positive synergy between sampling techniques (e.g., undersampling or SMOTE) and Bagging ensemble learning algorithm.

Why is difficult to learn in imbalanced domains?

- Preprocessing and cost sensitive learning have a similar behavior.
- Performance can still be improved, but we must analyze in deep the nature of the imbalanced data-set problem:
 - Imbalance ratio is not a determinant factor

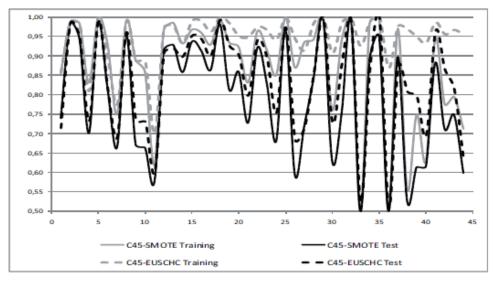

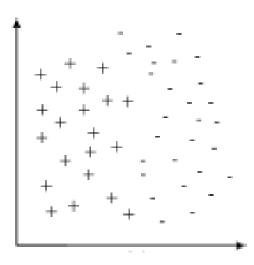

Fig. 4 C4.5 AUC in Training/Test sorted by IR

Class imbalance is not the only responsible of the lack in accuracy of an algorithm.

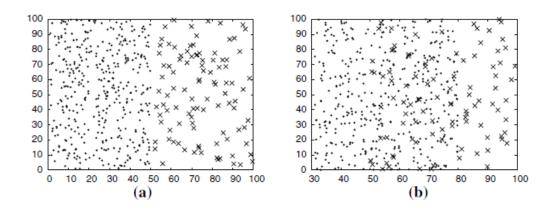

The class <u>overlapping</u> also influences the behaviour of the algorithms, and it is very typical in these domains.

60 %	.4200	1.000	.7100
80 %	.2100	.9989	.6044
100 %	.0000	1.000	.5000

Overlapping

V. García, R.A. Mollineda, J.S. Sánchez. On the k-NN performance in a challenging scenario of imbalance and overlapping. Pattern Anal Applic (2008) 11: 269-280

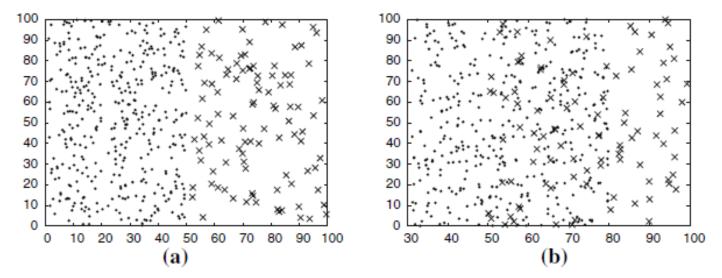

Fig. Two different levels of class overlapping: a 0% and b 60%

Experiment I: The positive examples are defined on the X-axis in the range [50-100], while those belonging to the majority class are generated in [0-50] for 0% of class overlap, [10-60] for 20%, [20-70] for 40%, [30-80] for 60%, [40-90] for 80%, and [50-100] for 100% of overlap.

The overall imbalance ratio matches the imbalance ratio corresponding to the overlap region, what could be accepted as a common case.

Overlapping

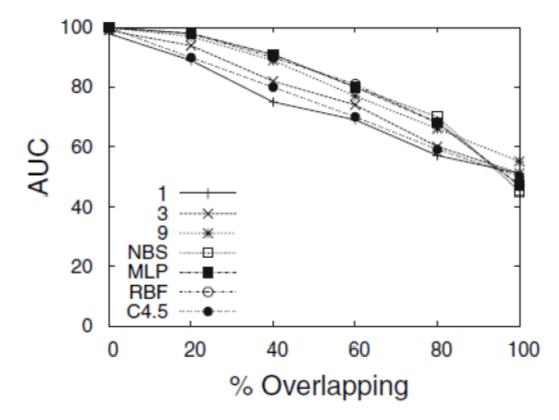

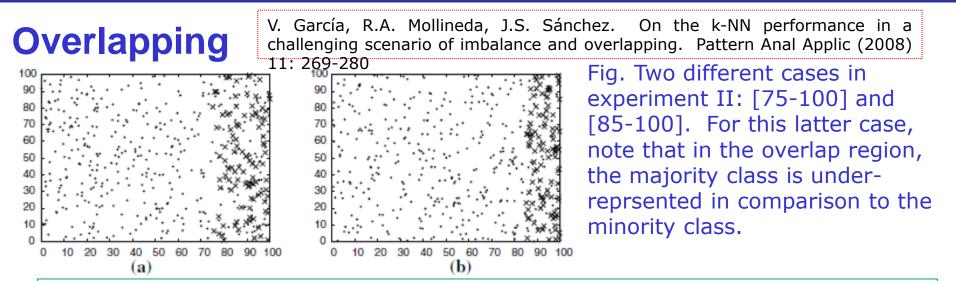

Fig. Performance metrics in k-NN rule and other learning algorithms for experiment I

Experiment II: The second experiment has been carried out over a collection of five artificial imbalanced data sets in which the overall minority class becomes the majority in the overlap region. To this end, the 400 negative examples have been defined on the X-axis to be in the range [0–100] in all data sets, while the 100 positive cases have been generated in the ranges [75–100], [80–100], [85–100], [90–100], and [95–100]. The number of elements in the overlap region varies from no local imbalance in the first case, where both classes have the same (expected) number of patterns and density, to a critical inverse imbalance in the fifth case, where the 100 minority examples appears as majority in the overlap region along with about 20 expected negative examples.

Overlapping

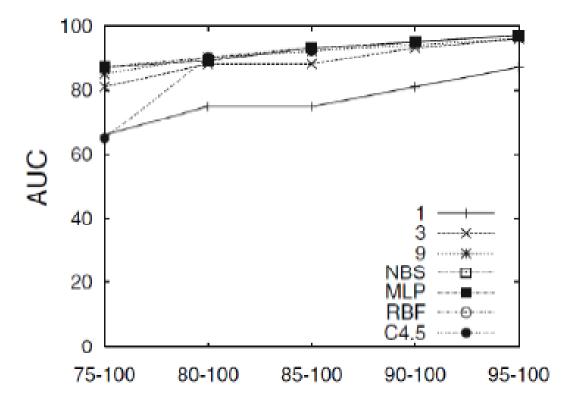

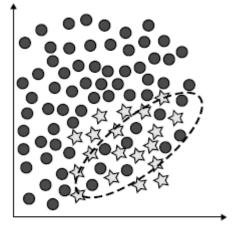

Fig. Performance metrics in k-NN rule and other learning algorithms for experiment II

Overlapping

Conclusions: Results (in this paper) show that the class more represented in overlap regions tends to be better classified by

(a) Class overlapping

represented in such regions tends to be better classified by local methods.

In this sense, as the value of k of the k-NN rule increases, along with a weakening of its local nature, it was progressively approaching the behaviour of global models.

Overlapping

Small disjuncts/rare data sets

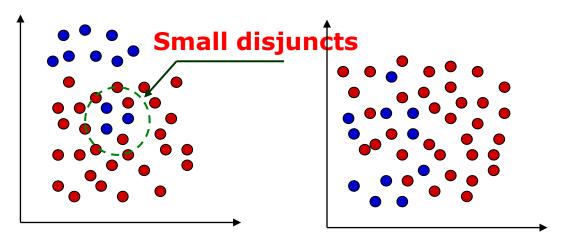

Density: Lack of data

Bordeline and Noise data

Dataset shift

V. López, A. Fernandez, S. García, V. Palade, F. Herrera, **An Insight into Classification with Imbalanced Data: Empirical Results and Current Trends on Using Data Intrinsic Characteristics.** Information Sciences 250 (2013) 113-141.

Class imbalance is not the only responsible of the lack in accuracy of an algorithm.

Class imbalances may yield <u>small disjuncts</u> which, in turn, will cause degradation.

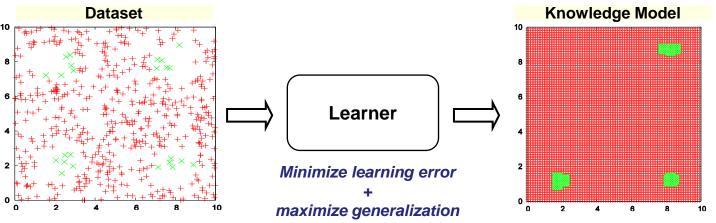

<u>Rare cases or Small disjuncts</u> are those disjuncts in the learned classifier that cover few training examples.

T. Jo, N. Japkowicz. Class imbalances versus small disjuncts. SIGKDD Explorations 6:1 (2004) 40-49 G.M. Weiss. Mining with Rarity: A Unifying Framework. SIGKDD Explorations 6:1 (2004) 7-19

Why is difficult to learn in imbalanced domains?

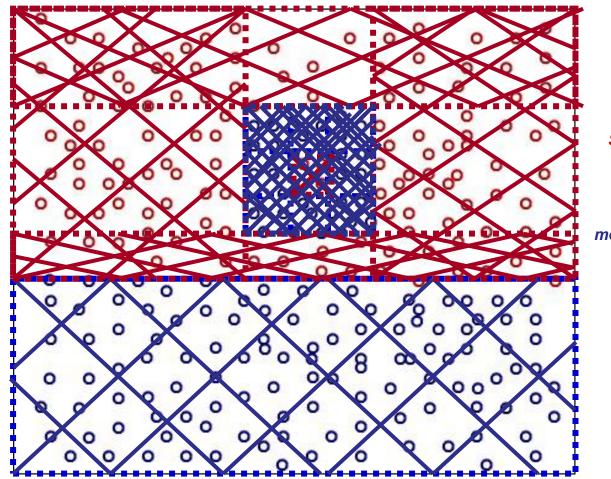

Rare or exceptional cases correspond to small numbers of training examples in particular areas of the feature space. When learning a concept, the presence of rare cases in the domain is an important consideration. The reason why rare cases are of interest is that they cause small disjuncts to occur, which are known to be more error prone than large disjuncts.

In the real world domains, rare cases are unknown since high dimensional data cannot be visualized to reveal areas of low coverage.

Rare or exceptional cases

Rare cases or Small disjunct: Focusing the problem

Small Disjunct or Starved niche

Again more small disjuncts

Overgeneral Classifier

Rare or exceptional cases

Rarity: Rare Cases versus Rare Classes

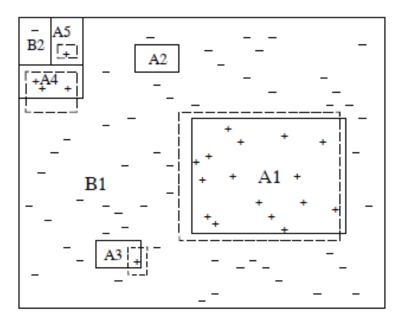

Figure 1: Graphical representation of a rare class and rare case

Class A is the rare (minority class and B is the common (majority class).

Subconcepts A2-A5 correspond to rare cases, whereas A1 corresponds to a fairly common case, covering a substantial portion of the instance space.

Subconcept B2 corresponds to a rare case, demonstrating that common classes may contain rare cases.

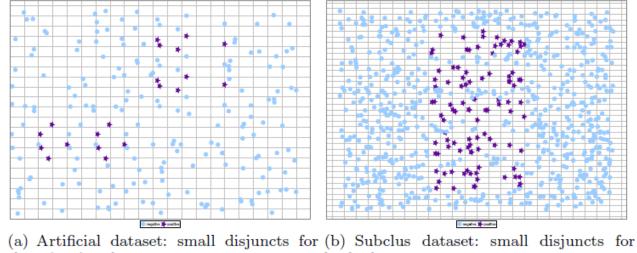

G.M. Weiss. Mining with Rarity: A Unifying Framework. SIGKDD Explorations 6:1 (2004) 7-19

Small disjuncts/Rare or exceptional cases

In the real-word domains, rare cases are not easily identified.An approximation is to use a clustering algorithm on each class. Jo and Japkowicz, 2004: Cluster-based oversampling: A method for inflating small disjuncts.

Once the training examples of each class have been clustered, oversampling starts. In the majority class, all the clusters, except for the largest one, are randomly oversampled so as to get the same number of training examples as the largest cluster. Let *maxclasssize* be the overall size of the large class. In the minority class, each cluster is randomly oversampled until each cluster contains *maxclasssize/Nsmallclass* where *Nsmallclass* represents the number of subclusters in the small class. CBO method: Cluster-based resampling identifies rare cases and resamples them individually, so as to avoid the creation of small disjuncts in the learned hypothesis.

Small disjuncts/Rare or exceptional cases

the minority class both classes

Fig. 5 Example of small disjuncts on imbalanced data

Table 12 Performance obtained by C4.5 in datasets suffering from small disjuncts

Dataset	Original Data			Preprocessed Data with CBO		
	TP_{rate}	TN_{rate}	AUC	TP_{rate}	TN_{rate}	AUC
Artificial dataset	.0000	1.000	.5000	1.000	1.000	1.000
Subclus dataset	1.000	.9029	.9514	1.000	1.000	1.000

Rare or exceptional cases

- Small disjuncts play a role in the performance loss of class imbalanced domains.
- Jo and Japkowicz results show that it is the small disjuncts problem more than the class imbalance problem that is responsible for the this decrease in accuracy.
- The performance of classifiers, though hindered by class imbalanced, is repaired as the training set size increases.

An open question: Whether it is more effective to use solutions that address both the class imbalance and the small disjunct problem simultaneously than it is to use solutions that address the class imbalance problem or the small disjunct problem, alone.

Overlapping

Small disjuncts/rare data sets

Density: Lack of data

Dataset shift

Basic assumption in classification:

Dataset shift

But sometimes....

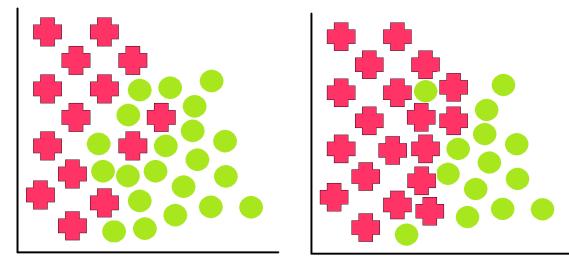

- The classifier has an overfitting problem.
- Is there a change in data distribution between training and test sets (Data fracture)?.

The Problem of Dataset Shift

- The classifier has an overfitting problem.
 - Change the parameters of the algorithm.
 - Use a more general learning method.
- There is a change in data distribution between training and test sets (Dataset shift).
 - Train a new classifier for the test set.
 - Adapt the classifier.
 - Modify the data in the test set ...

The Problem of Dataset Shift

The problem of data-set shift is defined as the case where training and test data follow different distributions.

J. G. Moreno-Torres, T. R. Raeder, R. Aláiz-Rodríguez, N. V. Chawla, F. Herrera, A unifying view on dataset shift in classification. *Pattern Recognition* 45:1 (2012) 521-530, doi:10.1016/j.patcog.2011.06.019.

Dataset shift

This is a common problem that can affect all kind of classification problems, and it often appears due to sample selection bias issues.

However, the data-set shift issue is specially relevant when dealing with imbalanced classification, because in highly imbalanced domains, the minority class is particularly sensitive to singular classification errors, due to the typically low number of examples it presents.

In the most extreme cases, a single misclassified example of the minority class can create a significant drop in performance.

Dataset shift

Since dataset shift is a **highly relevant issue in imbalanced classification**, it is easy to see why it would be an interesting perspective to focus on future research regarding the topic.

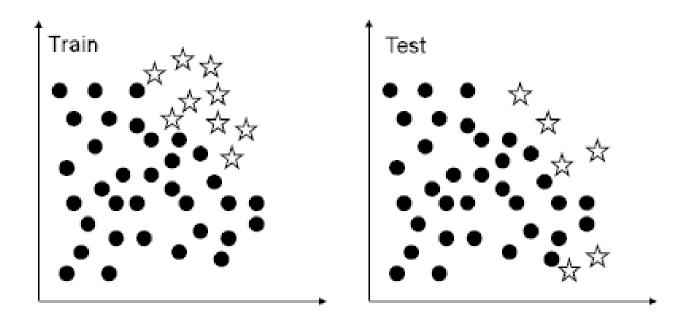

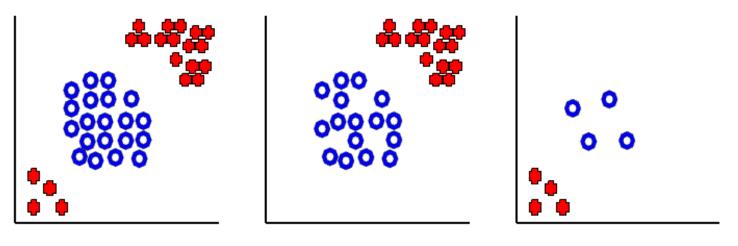

Figure 18: Example of the impact of data-set shift in imbalanced domains.

We comment on some of the most common causes of Dataset Shift:

Sample selection bias and non-stationary environments.

These concepts have created confusion at times, so it is important to remark that these terms are factors that can lead to the appearance of some of the shifts explained, but they do not constitute Dataset Shift themselves.

Sample selection bias:

Where Does the Difference Come from?

Dataset shift

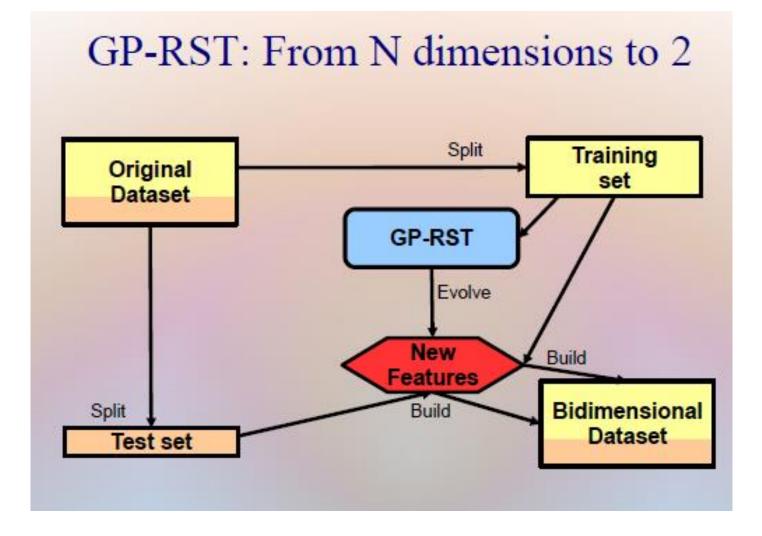

GP-RST: From N dimensions to 2

- Goal: obtain a 2-dimensional representation of a given dataset that is as separable as possible.
- Genetic Programming based: evolves 2 trees simultaneously as arithmetic functions of the previous N-dimensions.
- Evaluation of an individual dependant on Rough Set Theory measures.

Moreno-Torres, J. G., & Herrera, F. (2010). A preliminary study on overlapping and data fracture in imbalanced domains by means of genetic programming-based feature extraction. In *Proceedings of the 10th International Conference on Intelligent Systems Design and Applications (ISDA 2010) (pp. 501–506).*

Data-set shift

The quality of approxim $\gamma(x)$ n is the proportion of the elements of a rough set that belong to its lower approximation.

$$B_*(X) = \{x \in X : R'(x) \subseteq X\}$$

$$\gamma(x) = \frac{|B_*(X)|}{|X|}$$

Algorithm 1 Fitness evaluation procedure

1. Obtain $E' = \{e'^h = (f_1(e^h), f_2(e^h), C^h)/h = 1, ..., n_e\}$, where f_1 and f_2 are the expressions encoded on each of the trees of the individual being evaluated.

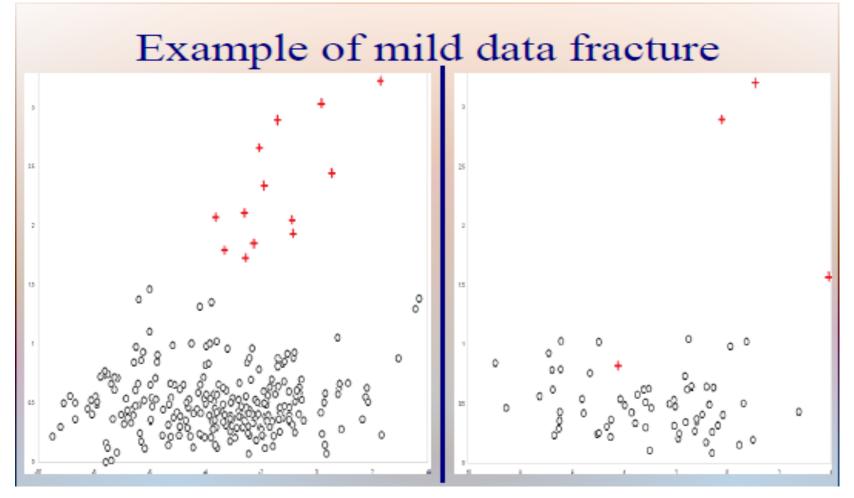

- 2. For each class label $C_i \in C$: $i = 1, ..., n_c$,
 - 2.1 Build a rough set X_i containing all the elements of class C_i.
 - 2.2 Calculate the lower approximation of X_i , $B_*(X_i)$.
 - 2.3 The fitness of the chromosome for class C_i is estimated as the quality of the approximation over X_i, γ(X_i).
- 3. The fitness of the chromosome is the geometric mean of the ones obtained for each class: $fitness = \sqrt[n_c]{\prod_{i=1}^{n_c} \gamma(X_i)}$.

Dataset shift

There are two different potential approaches in the study of the effect and solution of data-set shift in imbalanced domains.

□ The first one focuses on intrinsic data-set shift, that is, the data of interest includes some degree of shift that is producing a relevant drop in performance. In this case, we need to:

 Develop techniques to discover and measure the presence of data-set shift adapting them to minority classes.
 Design algorithms that are capable of working under data-set shift conditions. These could be either preprocessing techniques or algorithms that are designed to have the capability to adapt and deal with dataset shift without the need for a preprocessing step.

Data-set shift

The second branch in terms of data-set shift in imbalanced classification is related to induced data-set shift. Most current state of the art research is validated through stratified cross-validation techniques, which are another potential source of shift in the machine learning process.

A more suitable validation technique needs to be developed in order to avoid introducing data-set shift issues artificially.

Dataset shift

Imbalanced classification problems are difficult when overlap and/or data fracture are present.

- Single outliers can have a great influence on classifier performance.
- □ This is a novel problem in imbalanced classification that need a lot of studies.

Why is difficult to learn in imbalanced domains?

Intrinsic data characteristics

What domain characteristics aggravate the problem?

Overlapping

Rare sets/ Small disjuncts: The class imbalance problem may not be a problem in itself. Rather, the small disjunct problem it causes is responsible for the decay.

□ The overall size of the training set

large training sets yield low sensitivity to class imbalances

Noise and border data provokes additional problems.
 An increase in the degree of class imbalance. The data partition provokes data fracture: Dataset shift.

- II. Why is difficult to learn in imbalanced domains? Intrinsic data characteristics
- **III.** Class imbalance: Data sets, implementations, ...
- **IV.** Class imbalance: Trends and final comments

Class Imbalance: Trends and final comments Data level vs algorithm Level

Class Imbalance: Trends and final comments New studies, trends and challenges

- Improvements on resampling specialized resampling
 - New approches for creating artificial instances
 - How to choose the amount to sample?
 - New hybrid approaches oversampling vs undersampling
- Cooperation between resampling/cost sensitive/boosting
- Cooperation between feature selection and resampling
- Scalability: high number of features and sparse data
- Intrinsic data characteristics. To analyze the challenges on the class distribution.

Class Imbalance: Trends and final comments New studies, trends and challenges

In short, it is necessary to do work for:

- Establishing some fundamental results regarding: a) the nature of the problem,
- b) the behaviour of different types of classifiers, and
- c) the relative performance of various previously proposed schemes for dealing with the problem.

Designing new methods addressing the problem. Tackling data preprocessing and changing rule classification strategy.

Class Imbalance: Trends and final comments Final comments

Class imbalance is a challenging and critical problem in the knowledge discovery field, the classification with imbalanced data sets.

Due to the intriguing topics and tremendous potential applications, the classification of imbalanced data will continue to receive more and more attention along next years. Class of interest is often much smaller or rarer (minority class).
